XI BIENAL DE MATEMÁTICA 2024

Replace the wild population of mosquito *Ae. aegypti* by an infectious one carrying the *Wolbachia* bacteria in order to block *flavivirus* transmission.

Two parameters: maternal inheritance and cytoplasmic incompatibility (CI)

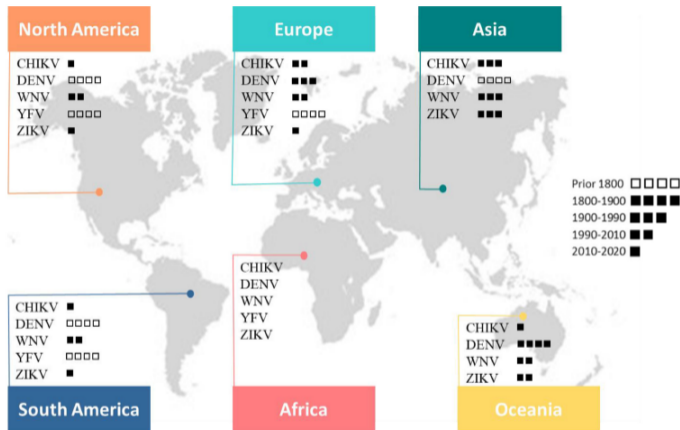

unidirectional

Table: Parameters of the mathematical model, their meaning, and units. The indices u , w , and J are related to uninfected, infected with *Wolbachia*, and immature (juvenile) phase, respectively.

Notation	Meaning	Units
ξ	maternal inheritance	-
τ	development time	days
q	cytoplasmic incompatibility	-
η	carrying capacity	individual ⁻¹
r_u, r_w	sex ratios	-
b_u, b_w	birth rates	days ⁻¹
θ, θ_J	rates of <i>Wolbachia</i> infection loss	days ⁻¹
d_u, d_w, d_{uJ}, d_{wJ}	rates of mortality	days ⁻¹
ϵ	mating competitive advantage	-

States variables

N_u and N_w the total uninfected and infected mosquito population, respectively.

$$\begin{aligned} \frac{dN_u(t)}{dt} &= r_u(1 - q\nu(t - \tau(t)))b_u(T(t - \tau(t)))N_u(t - \tau(t))S_u(t)\phi(T(t - \tau(t))) \\ &\quad + (1 - \xi\sigma(t))r_w b_w(T(t - \tau(t)))N_w(t - \tau(t))S_w(t)\phi(T(t - \tau(t))) \\ &\quad - d_u(T(t))N_u(t) + \theta(T(t))N_w(t), \\ \frac{dN_w(t)}{dt} &= r_w\xi\sigma(t)b_w(T(t - \tau(t)))N_w(t - \tau(t))S_w(t)\phi(T(t - \tau(t))) \\ &\quad - (\theta(T(t)) + d_w(T(t)))N_w(t), \end{aligned} \tag{1}$$

where

$$\phi(T(t - \tau(t))) = e^{-\eta(T(t - \tau(t)))(r_u N_u(t - \tau(t)) + r_w N_w(t - \tau(t)))}$$

and

$$\nu(t - \tau(t)) = \frac{(1 - r_w)N_w(t - \tau(t))}{\epsilon(1 - r_u)N_u(t - \tau(t)) + (1 - r_w)N_w(t - \tau(t))}.$$

Non-autonomous delay differential model

Parameters

S_i - survival of the immature phase, not carrying ($i = u$) or carrying ($i = w$) the bacterium;

σ - survival of the infection during the immature phase;

τ - development time.

$$\begin{aligned}\frac{dS_u(t)}{dt} &= S_u(t) \left[\frac{m(\tau(t))d_{uj}(\tau(t - \tau(t)))}{m(\tau(t - \tau(t)))} - d_{uj}(\tau(t)) \right], \\ \frac{dS_w(t)}{dt} &= S_w(t) \left[\frac{m(\tau(t))d_{wj}(\tau(t - \tau(t)))}{m(\tau(t - \tau(t)))} - d_{wj}(\tau(t)) \right], \\ \frac{d\sigma(t)}{dt} &= \sigma(t) \left[\frac{m(\tau(t))\theta_j(\tau(t - \tau(t)))}{m(\tau(t - \tau(t)))} - \theta_j(\tau(t)) \right], \\ \frac{d\tau(t)}{dt} &= 1 - \frac{m(\tau(t))}{m(\tau(t - \tau(t)))}.\end{aligned}$$

Theorem (Existence of the steady states)

If $T := T(t) = T(t - \tau)$, $\nu := \nu(t - \tau)$, and $r := r_u = r_w$, then System (1) admits three equilibria:

(i) $P_1 = (0, 0)$ which always exists;

(ii) $P_2 = \left(\frac{\ln R_u}{r\eta(T)}, 0 \right)$ that exists if $R_u > 1$;

(iii) $P_3 = \left(\frac{\ln R_w}{r\eta(T)} \left(\frac{R_{wu} + \alpha R_w}{R_{wu} + R_w(\alpha + 1) - R_u} \right), \frac{\ln R_w}{r\eta(T)} \left(\frac{R_w - R_u}{R_{wu} + R_w(\alpha + 1) - R_u} \right) \right)$ that exists
if $R_w > \max\{1, R_u\}$, where $\alpha := \alpha(T) = \frac{\theta(T)}{d_u(T)}$.

The three thresholds R_w , R_u and R_{wu} are given by

$$R_w = \frac{r\xi\sigma b_w(T)S_w}{\theta(T) + d_w(T)}, \quad R_u = \frac{r(1 - q\nu)b_u(T)S_u}{d_u(T)} \quad \text{and} \quad R_{wu}(T) = \frac{(1 - \xi\sigma)b_w(T)rS_w}{d_u(T)}.$$

where $S_w := S_w(t)$, $S_u := S_u(t)$ and $\sigma := \sigma(t)$.

Theorem (Local asymptotic stability of the equilibrium P_1)

Suppose that $T := T(t) = T(t - \tau)$, $\nu := \nu(t - \tau)$, and $r := r_u = r_w$. If $\max\{R_u, R_w\} < 1$, then P_1 is local asymptotic stable; otherwise it is unstable.

Theorem (Local asymptotic stability of the equilibrium P_2)

Suppose that $T := T(t) = T(t - \tau)$, $\nu := \nu(t - \tau)$, and $r := r_u = r_w$. If $R_u > \max\{1, R_w\}$, $R_w/R_u < \tan(\omega_1) \sin(\omega_1) + \cos(\omega_1)$ where $\omega_1 = -(\theta(T) + d_w(T))\tau \tan(\omega_1)$ and $1 - \ln R_u < \tan(\omega_2) \sin(\omega_2) + \cos(\omega_2)$ with $\omega_2 = -d_u(T)\tau \tan(\omega_2)$, $\omega_1, \omega_2 \in]0, \pi[$, then P_2 is local asymptotic stable; otherwise it is unstable.

Theorem (Local asymptotic stability of the equilibrium P_3)

Suppose that $T := T(t) = T(t - \tau)$, $\nu := \nu(t - \tau)$, $\theta(T) = 0$, $\xi\sigma = 1$, and $r := r_u = r_w$. If $R_w > \max\{1, R_u\}$, $R_u/R_w < \tan(\omega_1) \sin(\omega_1) + \cos(\omega_1)$ where $\omega_1 = -d_u(T)\tau \tan(\omega_1)$ e $1 - \ln R_w < \tan(\omega_2) \sin(\omega_2) + \cos(\omega_2)$ with $\omega_2 = -d_w(T)\tau \tan(\omega_2)$, $\omega_1, \omega_2 \in]0, \pi[$, then P_3 is local asymptotic stable; otherwise it is unstable.

Temperature-driven parameters

Temperature-driven parameters

What is the best period of the year to release the *Wolbachia*-carrying mosquitoes?

Assuming a periodic variation of temperature over a year, the temperature function is given by

$$T(t) = T_M - \sigma_T \cos\left(\frac{2\pi t}{365}\right)$$

where T_M and σ_T are the mean temperature and its variation.

The initial condition is $N_u(t) = 200 + 200 \left| \cos\left(t + \frac{\pi}{2}\right) \right|$, and $N_w(t) = 0$, for $t \in [-\tau, 0]$, $S_u(0) = e^{-\tau(0)d_{uu}(T(0))}$, $S_w(0) = e^{-\tau(0)d_{ww}(T(0))}$, and $\sigma(0) = e^{-\tau(0)\theta_j(T(0))}$ with $\tau(0) = m(T(0))^{-1}$.

What much and how many times we will do it?

One release of *Wolbachia*-carrying mosquitoes during favorable or not favorable period.

Figure: unfavorable period

Figure: favorable period

What much and how many times we will do it?

Four releases of *Wolbachia*-carrying mosquitoes during favorable or not favorable period.

Figure: unfavorable period

Figure: favorable period

How can we measure the efficiency of the technique?

$$E_k = 1 - \frac{I_c}{I_0}, \quad \text{with } I_j = \int_{t_i}^{t_f} N_u(t) dt$$

where I_j with $j = \{0, c\}$ measures the cumulative number of non-infected mosquitoes observed between t_i and t_f .

Figure: $T = 32 \pm 3^\circ\text{C}$

The effect of the bacteria strain

Temperature data in Niterói-RJ from 2020 to 2022 and the dynamics of both populations.

Figure: From 2020 to 2022

Figure: non-infected one

Figure: $\xi = 0.99$ and $q = 0.95$

Figure: $\xi = 0.99$ and $q = 0.8$

What is the importance of the chosen bacterial strain?

Conclusions

- Four releases delayed by seven days each are more efficient than one.
- When the mosquito population is high is the best moment to implement the releasing of infected mosquitoes.
- Strains with high levels of cytoplasmic incompatibility and maternal inheritance boost the efficacy of the technique.
- High temperature can increase the ratio of infected to non-infected mosquitoes necessary to achieve infection's persistence.
- High temperature can also diminishing the prevalence of the infection in the long run.

Although, the general idea of how all these factors affects the efficacy of the technique, the interaction among them are not trivial. And here, a framework of how this interaction affects the replacement of wild mosquito population by an infected one that is not able to transmit dengue is developed.

Thank you!
